

Cardano.BM - benchmarking and logging

Alexander Diemand

Andreas Triantafyllos

November 2018

Abstract

This is a framework that combines logging, benchmarking and monitoring. Complex evaluations of STM or monadic actions can be observed from outside while reading operating system counters before and after, and calculating their differences, thus relating resource usage to such actions. Through interactive configuration, the runtime behaviour of logging or the measurement of resource usage can be altered. Further reduction in logging can be achieved by redirecting log messages to an aggregation function which will output the running statistics with less frequency than the original message.

Chapter 1

Cardano BM

1.1 Overview

In figure 1.1 we display the relationships among modules in *Cardano.BM*. The arrows indicate import of a module. The arrows with a triangle at one end would signify "inheritance" in object-oriented programming, but we use it to show that one module replaces the other in the namespace, thus refines its interface.

1.2 Introduction

1.2.1 Logging with **Trace**

1.2.2 Setup procedure

Hierarchy of **Traces**

1.2.3 Measuring *Observables*

1.2.4 Information reduction in **Aggregation**

1.2.5 Output selection

1.2.6 Monitoring

1.3 Examples

1.3.1 Observing evaluation of a STM action

1.3.2 Observing evaluation of a monad action

1.3.3 Simple example showing plain logging

```
{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import Cardano.BM.Configuration.Static (defaultConfigStdout)
```

```
import Cardano.BM.Setup (setupTrace)
import Cardano.BM.Trace (logDebug, logError, logInfo, logNotice,
                        logWarning)

main :: IO ()
main = do
  c ← defaultConfigStdout
  tr ← setupTrace (Right c) "simple"

  logDebug tr "this is a debug message"
  logInfo   tr "this is an information."
  logNotice tr "this is a notice!"
  logWarning tr "this is a warning!"
  logError  tr "this is an error!"

  threadDelay 80000
```

Figure 1.2: Setup procedure

```
return ()
```

1.3.4 Complex example showing logging, aggregation of log items, and observing IO actions

Module header and import directives

```

{-# LANGUAGE OverloadedStrings #-}
module Main
  (main)
  where
import Control.Concurrent (threadDelay)
import qualified Control.Concurrent.Async as Async
import Control.Monad (forM, forM_)
import GHC.Conc.Sync (STM, TVar, atomically, newTVar, readTVar, writeTVar)
import Data.Text (pack)
import Network.Download (openURI)
import System.Random
import qualified Data.ByteString.Char8 as BS8
import qualified Cardano.BM.Configuration.Model as CM
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.BackendKind
import Cardano.BM.Data.LogItem
import Cardano.BM.Data.Observable
import Cardano.BM.Data.Output
import Cardano.BM.Data.Severity
import Cardano.BM.Data.SubTrace
import Cardano.BM.Observer.Monad (bracketObserveIO)
import qualified Cardano.BM.Observer.STM as STM
import Cardano.BM.Setup
import Cardano.BM.Trace
  
```

Define configuration

The output can be viewed in EKG on <http://localhost:12789>.

```

config :: IO CM.Configuration
config = do
  c ← CM.empty
  CM.setMinSeverity c Debug
  CM.setSetupBackends c [KatipBK, AggregationBK, EKGViewBK]
  {-per default each messages is sent to the logs, if not otherwise defined (see below: 'CM.setBackend') -}

```

1.4 Code listings

1.4.1 Cardano.BM.Observer.STM

```
stmWithLog :: STM.STM (t,[LogObject]) → STM.STM (t,[LogObject])
stmWithLog action = action
```

Observe STM action in a named context

With given name, create a **SubTrace** according to **Configuration** and run the passed STM action on it.

```
bracketObserveIO :: Trace IO → Text → STM.STM t → IO t
bracketObserveIO logTrace0 name action = do
  logTrace ← subTrace name logTrace0
  let subtrace = typeofTrace logTrace
  bracketObserveIO' subtrace logTrace action
where
  bracketObserveIO' :: SubTrace → Trace IO → STM.STM t → IO t
  bracketObserveIO' NoTrace _ act =
    STM.atomically act
  bracketObserveIO' subtrace logTrace act = do
    mCountersid ← observeOpen subtrace logTrace
    -- run action; if an exception is caught will be logged and rethrown.
    t ← (STM.atomically act) 'catch' (λ(e :: SomeException) → (logError logTrace (pack (show e)) >> throwM e))
    case mCountersid of
      Left openException →
        -- since observeOpen faced an exception there is no reason to call observeClose
        -- however the result of the action is returned
        logNotice logTrace ("ObserveOpen: " <> pack (show openException))
      Right countersid → do
        res ← observeClose subtrace logTrace countersid [ ]
        case res of
          Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
          _ → pure ()
    pure t
```

Observe STM action in a named context and output captured log items

The STM action might output messages, which after "success" will be forwarded to the logging trace. Otherwise, this function behaves the same as **Observe STM action in a named context**.

```
bracketObserveLogIO :: Trace IO → Text → STM.STM (t,[LogObject]) → IO t
bracketObserveLogIO logTrace0 name action = do
  logTrace ← subTrace name logTrace0
  let subtrace = typeofTrace logTrace
  bracketObserveLogIO' subtrace logTrace action
```

where

```

bracketObserveLogIO' :: SubTrace → Trace IO → STM.STM (t, [LogObject]) → IO t
bracketObserveLogIO' NoTrace _ act = do
  (t, _) ← STM.atomically $ stmWithLog act
  pure t
bracketObserveLogIO' subtrace logTrace act = do
  mCountersid ← observeOpen subtrace logTrace
  -- run action, return result and log items; if an exception is
  -- caught will be logged and rethrown.
  (t, as) ← (STM.atomically $ stmWithLog act) 'catch'
    (λ(e :: SomeException) → (logError logTrace (pack (show e)) >> throwM e))
  case mCountersid of
    Left openException →
      -- since observeOpen faced an exception there is no reason to call observeClose
      -- however the result of the action is returned
      logNotice logTrace ("ObserveOpen: " <> pack (show openException))
    Right countersid → do
      res ← observeClose subtrace logTrace countersid as
      case res of
        Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
        _ → pure ()
  pure t

```

1.4.2 Cardano.BM.Observer.Monad

Monadic.bracketObserverIO

Observes an *IO* action and adds a name to the logger name of the passed in **Trace**. An empty *Text* leaves the logger name untouched.

Microbenchmarking steps:

1. Create a *trace* which will have been configured to observe things besides logging.

```

import qualified Cardano.BM.Configuration.Model as CM
ooo
c ← config
trace@(ctx, _) ← setupTrace (Right c) "demo-playground"
where
  config :: IO CM.Configuration
  config = do
    c ← CM.empty
    CM.setMinSeverity c Debug
    CM.setSetupBackends c [KatipBK, AggregationBK]
    CM.setDefaultBackends c [KatipBK, AggregationBK]
    CM.setSetupScribes c [ScribeDefinition {
      scName = "stdout"
      , scKind = StdoutSK
    }]

```

```

    ,scRotation = Nothing
  }
]
CM.setDefaultScribes c [ "StdoutSK: : stdout" ]
return c

```

2. *c* is the **Configuration** of *trace*. In order to enable the collection and processing of measurements (min, max, mean, std-dev) *AggregationBK* is needed.

```
CM.setDefaultBackends c [ KatipBK, AggregationBK ]
```

in a configuration file (YAML) means

```

defaultBackends:
- KatipBK
- AggregationBK

```

3. Set the measurements that you want to take by changing the configuration of the *trace* using *setSubTrace*, in order to declare the namespace where we want to enable the particular measurements and the list with the kind of measurements.

```

CM.setSubTrace
  (configuration ctx)
  "demo-playground.submit-tx"
  (Just $ ObservableTrace observablesSet)
where
  observablesSet = [ MonotonicClock, MemoryStats ]

```

4. Find an action to measure. e.g.:

```
runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())
```

and use **bracketObserveIO**. e.g.:

```

bracketObserveIO trace "submit-tx" $
  runProtocolWithPipe x hdl proto 'catch' (λProtocolStopped → return ())

```

```

bracketObserveIO :: Trace IO → Text → IO t → IO t
bracketObserveIO logTrace0 name action = do
  logTrace ← subTrace name logTrace0
  bracketObserveIO' (typeofTrace logTrace) logTrace action
where
  bracketObserveIO' :: SubTrace → Trace IO → IO t → IO t
  bracketObserveIO' NoTrace _ act = act
  bracketObserveIO' subtrace logTrace act = do
    mCountersid ← observeOpen subtrace logTrace
    -- run action; if an exception is caught will be logged and rethrown.
    t ← act 'catch' (λ(e :: SomeException) → (logError logTrace (pack (show e)) >> throwM e))

```

```

case mCountersid of
  Left openException →
    -- since observeOpen faced an exception there is no reason to call observeClose
    -- however the result of the action is returned
    logNotice logTrace ("ObserveOpen: " <> pack (show openException))
  Right countersid → do
    res ← observeClose subtrace logTrace countersid [ ]
    case res of
      Left ex → logNotice logTrace ("ObserveClose: " <> pack (show ex))
      _ → pure ()
    pure t

```

Monadic.bracketObserverM

Observes a *MonadIO* $m \Rightarrow m$ action and adds a name to the logger name of the passed in **Trace**. An empty *Text* leaves the logger name untouched.

```

bracketObserveM :: (MonadCatch m, MonadIO m) => Trace IO → Text → m t → m t
bracketObserveM logTrace0 name action = do
  logTrace ← liftIO $ subTrace name logTrace0
  bracketObserveM' (typeofTrace logTrace) logTrace action
where
  bracketObserveM' :: (MonadCatch m, MonadIO m) => SubTrace → Trace IO → m t → m t
  bracketObserveM' NoTrace _ act = act
  bracketObserveM' subtrace logTrace act = do
    mCountersid ← liftIO $ observeOpen subtrace logTrace
    -- run action; if an exception is caught will be logged and rethrown.
    t ← act 'catch'
    (λ(e :: SomeException) → (liftIO (logError logTrace (pack (show e)) >> throwM e)))
    case mCountersid of
      Left openException →
        -- since observeOpen faced an exception there is no reason to call observeClose
        -- however the result of the action is returned
        liftIO $ logNotice logTrace ("ObserveOpen: " <> pack (show openException))
      Right countersid → do
        res ← liftIO $ observeClose subtrace logTrace countersid [ ]
        case res of
          Left ex → liftIO (logNotice logTrace ("ObserveClose: " <> pack (show ex)))
          _ → pure ()
        pure t

```

observerOpen

```

observeOpen :: SubTrace → Trace IO → IO (Either SomeException CounterState)
observeOpen subtrace logTrace = (do
  identifier ← newUnique

```

```

-- take measurement
counters ← readCounters subtrace
let state = CounterState identifier counters
-- send opening message to Trace
traceNamedObject logTrace $ ObserveOpen state
return (Right state) 'catch' (return ∘ Left)

```

observeClose

```

observeClose :: SubTrace → Trace IO → CounterState → [LogObject] → IO (Either SomeException ())
observeClose subtrace logTrace initState logObjects = (do
  let identifier = csIdentifier initState
      initialCounters = csCounters initState
  -- take measurement
  counters ← readCounters subtrace
  -- send closing message to Trace
  traceNamedObject logTrace $ ObserveClose (CounterState identifier counters)
  -- send diff message to Trace
  traceNamedObject logTrace $
    ObserveDiff (CounterState identifier (diffCounters initialCounters counters))
  -- trace the messages gathered from inside the action
  forM_ logObjects $ traceNamedObject logTrace
  return (Right ())) 'catch' (return ∘ Left)

```

1.4.3 BaseTrace

Contravariant

A covariant is a functor: $F A \rightarrow F B$

A contravariant is a functor: $F B \rightarrow F A$

$Op\ a\ b$ implements the inverse to 'arrow' " $getOp :: b \rightarrow a$ ", which when applied to a **BaseTrace** of type " $Op\ (m\ ())\ s$ ", yields " $s \rightarrow m\ ()$ ". In our case, Op accepts an action in a monad m with input type **LogNamed LogObject** (see 'Trace').

```
newtype BaseTrace m s = BaseTrace { runTrace :: Op (m ()) s }
```

contramap

A covariant functor defines the function " $fmap :: (a \rightarrow b) \rightarrow f\ a \rightarrow f\ b$ ". In case of a contravariant functor, it is the dual function " $contramap :: (a \rightarrow b) \rightarrow f\ b \rightarrow f\ a$ " which is defined.

In the following instance, $runTrace$ extracts type " $Op\ (m\ ())\ s$ " to which $contramap$ applies f , thus " $f\ s \rightarrow m\ ()$ ". The constructor **BaseTrace** restores " $Op\ (m\ ())\ (f\ s)$ ".

```
instance Contravariant (BaseTrace m) where
  contramap f = BaseTrace ∘ contramap f ∘ runTrace
```

traceWith

Accepts a **Trace** and some payload s . First it gets the contravariant from the **Trace** as type " $Op\ (m\ ())\ s$ " and, after " $getOp::b \rightarrow a$ " which translates to " $s \rightarrow m\ ()$ ", calls the action on the **LogNamed LogObject**.

```
traceWith :: BaseTrace m s → s → m ()
traceWith = getOp ∘ runTrace
```

natTrace

Natural transformation from monad m to monad n .

```
natTrace :: (forall x ∘ m x → n x) → BaseTrace m s → BaseTrace n s
natTrace nat (BaseTrace (Op tr)) = BaseTrace $ Op $ nat ∘ tr
```

noTrace

A **Trace** that discards all inputs.

```
noTrace :: Applicative m ⇒ BaseTrace m a
noTrace = BaseTrace $ Op $ const (pure ())
```

1.4.4 Cardano.BM.Trace**Utilities**

Natural transformation from monad m to monad n .

```
natTrace :: (forall x ∘ m x → n x) → Trace m → Trace n
natTrace nat (ctx, trace) = (ctx, BaseTrace.natTrace nat trace)
```

Access type of **Trace**.

```
typeofTrace :: Trace m → SubTrace
typeofTrace (ctx, _) = tracetype ctx
```

Update type of **Trace**.

```
updateTracetype :: SubTrace → Trace m → Trace m
updateTracetype subtr (ctx, tr) = (ctx { tracetype = subtr }, tr)
```

Enter new named context

The context name is created and checked that its size is below a limit (currently 80 chars). The minimum severity that a log message must be labelled with is looked up in the configuration and recalculated.

```
appendName :: MonadIO m ⇒ LoggerName → Trace m → m (Trace m)
appendName name (ctx, trace) = do
```

```

let prevLoggerName = loggerName ctx
    prevMinSeverity = minSeverity ctx
    newLoggerName = appendWithDot prevLoggerName name
    globMinSeverity ← liftIO $ Config.minSeverity (configuration ctx)
    namedSeverity ← liftIO $ Config.inspectSeverity (configuration ctx) newLoggerName
case namedSeverity of
  Nothing → return (ctx {loggerName = newLoggerName}, trace)
  Just sev → return (ctx {loggerName = newLoggerName
    , minSeverity = max (max sev prevMinSeverity) globMinSeverity}
    , trace)

appendWithDot :: LoggerName → LoggerName → LoggerName
appendWithDot "" newName = T.take 80 newName
appendWithDot xs "" = xs
appendWithDot xs newName = T.take 80 $ xs <> " ." <> newName

```

Contramap a trace and produce the naming context

```

named :: BaseTrace.BaseTrace m (LogNamed i) → LoggerName → BaseTrace.BaseTrace m i
named trace name = contramap (LogNamed name) trace

```

Trace a LogObject through

```

traceNamedObject
  :: MonadIO m
  ⇒ Trace m
  → LogObject
  → m ()

traceNamedObject trace@(ctx, logTrace) lo = do
  let lname = loggerName ctx
  doOutput ← case (typeofTrace trace) of
    FilterTrace filters → do
      return $ evalFilters filters lname lo
    TeeTrace secName → do
      -- create a newly named copy of the LogObject
      BaseTrace.traceWith (named logTrace (lname <> " ." <> secName)) lo
      return True
  _ → return True
  if doOutput
  then BaseTrace.traceWith (named logTrace lname) lo
  else return ()

```

Evaluation of FilterTrace

```

evalFilters :: [NameOperator] → LoggerName → LogObject → Bool
evalFilters nos nm lo =

```

```

any (evalFilter nm lo) nos
where
  evalFilter :: LoggerName → LogObject → NameOperator → Bool
  evalFilter name item (Drop sel) = ¬ (matchName name sel) ∧ ¬ (matchItem item sel)
  evalFilter name item (Unhide sel) = matchName name sel ∨ matchItem item sel
  matchName :: LoggerName → NameSelector → Bool

  matchItem (LP (LogValue name _)) (Named name') = name ≡ name'
  matchItem _ _ = False

```

Concrete Trace on stdout

This function returns a trace with an action of type "**(LogNamed LogObject) → IO ()**" which will output a text message as text and all others as JSON encoded representation to the console.

TODO remove *locallock*

```

locallock :: MVar ()
locallock = unsafePerformIO $ newMVar ()

stdoutTrace :: TraceNamed IO
stdoutTrace = BaseTrace.BaseTrace $ Op $ λlognamed →
  withMVar locallock $ \_ →
    case lnItem lognamed of
      LP (LogMessage logItem) →
        output (lnName lognamed) $ liPayload logItem
      obj →
        output (lnName lognamed) $ toStrict (encodeToLazyText obj)
where
  output nm msg = TIO.putStrLn $ nm <> " :: " <> msg

```

Concrete Trace into a TVar

```

traceInTVar :: STM.TVar [a] → BaseTrace.BaseTrace STM.STM a
traceInTVar tvar = BaseTrace.BaseTrace $ Op $ λa → STM.modifyTVar tvar ((:) a)
traceInTVarIO :: STM.TVar [LogObject] → TraceNamed IO
traceInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) (lnItem ln))
traceNamedInTVarIO :: STM.TVar [LogNamed LogObject] → TraceNamed IO
traceNamedInTVarIO tvar = BaseTrace.BaseTrace $ Op $ λln →
  STM.atomically $ STM.modifyTVar tvar ((:) ln)

```

Check a log item's severity against the **Trace**'s minimum severity

do we need three different **minSeverity** defined?

We do a lookup of the global **minSeverity** in the configuration. And, a lookup of the **minSeverity** for the current named context. These values might have changed in the meanwhile.

A third filter is the **minSeverity** defined in the current context.

```

traceConditionally
  :: MonadIO m
  ⇒ Trace m → LogObject
  → m ()
traceConditionally logTrace@(ctx, _) msg@(LP (LogMessage item)) = do
  globminsev ← liftIO $ Config.minSeverity (configuration ctx)
  globnamesev ← liftIO $ Config.inspectSeverity (configuration ctx) (loggerName ctx)
  let minsev = max (minSeverity ctx) $ max globminsev (fromMaybe Debug globnamesev)
      flag = (liSeverity item) ≥ minsev
  when flag $ traceNamedObject logTrace msg
traceConditionally logTrace logObject =
  traceNamedObject logTrace logObject

```

Enter message into a trace

The function **traceNamedItem** creates a **LogObject** and threads this through the action defined in the **Trace**.

```

traceNamedItem
  :: (MonadIO m)
  ⇒ Trace m
  → LogSelection
  → Severity
  → T.Text
  → m ()
traceNamedItem trace p s m =
  let logmsg = LP $ LogMessage $ LogItem {liSelection = p
    , liSeverity = s
    , liPayload = m
    }
  in
  traceConditionally trace $ logmsg

```

Logging functions

```

logDebug, logInfo, logNotice, logWarning, logError, logCritical, logAlert, logEmergency
  :: (MonadIO m) ⇒ Trace m → T.Text → m ()
logDebug   logTrace = traceNamedItem logTrace Both Debug
logInfo    logTrace = traceNamedItem logTrace Both Info

```

```

logNotice  logTrace = traceNamedItem logTrace Both Notice
logWarning logTrace = traceNamedItem logTrace Both Warning
logError   logTrace = traceNamedItem logTrace Both Error
logCritical logTrace = traceNamedItem logTrace Both Critical
logAlert   logTrace = traceNamedItem logTrace Both Alert
logEmergency logTrace = traceNamedItem logTrace Both Emergency

logEmergencyUnsafeP logTrace = traceNamedItem logTrace PublicUnsafe Emergency

```

subTrace

Transforms the input **Trace** according to the **Configuration** using the logger name of the current **Trace** appended with the new name. If the empty **Text** is passed, then the logger name remains untouched.

```

subTrace :: MonadIO m => T.Text → Trace m → m (Trace m)
subTrace name tr@(ctx, _) = do
  let newName = appendWithDot (loggerName ctx) name

```

```

subtrace0 ← liftIO $ Config.findSubTrace (configuration ctx) newName
let subtrace = case subtrace0 of Nothing → Neutral; Just str → str
case subtrace of
  Neutral      → do
    tr' ← appendName name tr

    case lnItem lognamed of
      ObserveOpen _ → return ()
      obj           → traceNamedObject tr obj)
  ObservableTrace _ → do
    tr' ← appendName name tr
    return $ updateTracetype subtrace tr'

```

1.4.5 Cardano.BM.Setup

Figure 1.3: Setup procedure

setupTrace

Setup a new **Trace** (**Trace**) with either a given **Configuration** (**Configuration.Model**) or a *FilePath* to a configuration file.

```

setupTrace :: MonadIO m => Either FilePath Config.Configuration → Text → m (Trace m)
setupTrace (Left cfgFile) name = do
  c ← liftIO $ Config.setup cfgFile
  setupTrace_ c name
setupTrace (Right c) name = setupTrace_ c name
setupTrace_ :: MonadIO m => Config.Configuration → Text → m (Trace m)
setupTrace_ c name = do
  sb ← liftIO $ Switchboard.realize c
  sev ← liftIO $ Config.minSeverity c
  ctx ← liftIO $ newContext name c sev sb
  let logTrace = natTrace liftIO (ctx, Switchboard.mainTrace sb)
  logTrace' ← subTrace " " logTrace
  return logTrace'

```

withTrace

```

withTrace :: MonadIO m => Config.Configuration → Text → (Trace m → m t) → m t
withTrace cfg name action = do
  logTrace ← setupTrace (Right cfg) name
  action logTrace

```

newContext

```

newContext :: LoggerName
  → Config.Configuration
  → Severity
  → Switchboard.Switchboard
  → IO TraceContext
newContext name cfg sev sb = do
  return $ TraceContext {
    loggerName = name
    , configuration = cfg
    , minSeverity = sev
    , tracetype = Neutral
    , shutdown = unrealize sb
  }

```

1.4.6 Cardano.BM.Counters

Here the platform is chosen on which we compile this program.

Currently, we mainly support *Linux* with its 'proc' filesystem.

```

{-# LANGUAGE CPP #-}
# if defined (linux_HOST_OS)

```

```

# define LINUX
# endif
module Cardano.BM.Counters
(
  Platform.readCounters
  ,diffTimeObserved
  ,getMonoClock
) where
# ifdef LINUX
import qualified Cardano.BM.Counters.Linux as Platform
# else
import qualified Cardano.BM.Counters.Dummy as Platform
# endif
import Cardano.BM.Counters.Common (getMonoClock)
import Cardano.BM.Data.Aggregated (Measurable (..))
import Cardano.BM.Data.Counter
import Data.Time.Units (Microsecond)

```

Calculate difference between clocks

```

diffTimeObserved :: CounterState → CounterState → Microsecond
diffTimeObserved (CounterState id0 startCounters) (CounterState id1 endCounters) =
  let
    startTime = getMonotonicTime startCounters
    endTime = getMonotonicTime endCounters
  in
    if (id0 ≡ id1)
    then endTime − startTime
    else error "these clocks are not from the same experiment"
where
  getMonotonicTime counters = case (filter isMonotonicClockCounter counters) of
    [(Counter MonotonicClockTime − (Microseconds micros))] → fromInteger micros
    _ → error "A time measurement is missing!"
  isMonotonicClockCounter :: Counter → Bool
  isMonotonicClockCounter = (MonotonicClockTime ≡) ∘ cType

```

1.4.7 Cardano.BM.Counters.Common

Common functions that serve *readCounters* on all platforms.

```

nominalTimeToMicroseconds :: Word64 → Microsecond
nominalTimeToMicroseconds = fromMicroseconds ∘ toInteger ∘ ('div' 1000)

```

Read monotonic clock

```

getMonoClock :: IO [Counter]
getMonoClock = do
  t ← getMonotonicTimeNSec
  return [Counter MonotonicClockTime "monoclock" $ Microseconds (toInteger $ nominalTimeToMicroseconds t)]

```

Read GHC RTS statistics

Read counters from GHC's *RTS* (runtime system). The values returned are as per the last GC (garbage collection) run.

```

readRTSStats :: IO [Counter]
readRTSStats = do
  iscollected ← GhcStats.getRTSStatsEnabled
  if iscollected
    then ghcstats
    else return []
  where
    ghcstats :: IO [Counter]
    ghcstats = do
      -- need to run GC?
      rts ← GhcStats.getRTSStats
      let getrts = ghcval rts
      return [getrts (toInteger ∘ GhcStats.allocated_bytes, "bytesAllocated")
            ,getrts (toInteger ∘ GhcStats.max_live_bytes, "liveBytes")
            ,getrts (toInteger ∘ GhcStats.max_large_objects_bytes, "largeBytes")
            ,getrts (toInteger ∘ GhcStats.max_compact_bytes, "compactBytes")
            ,getrts (toInteger ∘ GhcStats.max_slop_bytes, "slopBytes")
            ,getrts (toInteger ∘ GhcStats.max_mem_in_use_bytes, "usedMemBytes")
            ,getrts (toInteger ∘ GhcStats.gc_cpu_ns, "gcCpuNs")
            ,getrts (toInteger ∘ GhcStats.gc_elapsed_ns, "gcElapsedNs")
            ,getrts (toInteger ∘ GhcStats.cpu_ns, "cpuNs")
            ,getrts (toInteger ∘ GhcStats.elapsed_ns, "elapsedNs")
            ,getrts (toInteger ∘ GhcStats.gcs, "gcNum")
            ,getrts (toInteger ∘ GhcStats.major_gcs, "gcMajorNum")
            ]
    ghcval :: GhcStats.RTSStats → ((GhcStats.RTSStats → Integer), Text) → Counter
    ghcval s (f, n) = Counter RTSStats n $ PureI (f s)

```

1.4.8 Cardano.BM.Counters.Dummy

This is a dummy definition of *readCounters* on platforms that do not support the 'proc' filesystem from which we would read the counters.

The only supported measurements are monotonic clock time and RTS statistics for now.

```

readCounters :: SubTrace → IO [Counter]
readCounters NoTrace = return []

```

```

readCounters Neutral          = return [ ]
readCounters (TeeTrace _)     = return [ ]
readCounters (FilterTrace _) = return [ ]
readCounters UntimedTrace    = return [ ]
readCounters DropOpening     = return [ ]
readCounters (ObservableTrace tts) = foldrM ( $\lambda(sel, fun) a \rightarrow$ 
  if any ( $\equiv sel$ ) tts
  then ( $fun \gg \lambda xs \rightarrow return \$ a ++ xs$ )
  else return a) [ ] selectors
where
  selectors = [ (MonotonicClock, getMonoClock)
    -- , (MemoryStats, readProcStatM)
    -- , (ProcessStats, readProcStats)
    -- , (IOStats, readProcIO)
    , (GhcRtsStats, readRTSStats)
    ]

```

1.4.9 Cardano.BM.Counters.Linux

we have to expand the *readMemStats* function
to read full data from *proc*

```

readCounters :: SubTrace  $\rightarrow$  IO [Counter]
readCounters NoTrace          = return [ ]
readCounters Neutral          = return [ ]
readCounters (TeeTrace _)     = return [ ]
readCounters (FilterTrace _) = return [ ]
readCounters UntimedTrace    = return [ ]
readCounters DropOpening     = return [ ]
readCounters (ObservableTrace tts) = foldrM ( $\lambda(sel, fun) a \rightarrow$ 
  if any ( $\equiv sel$ ) tts
  then ( $fun \gg \lambda xs \rightarrow return \$ a ++ xs$ )
  else return a) [ ] selectors
where
  selectors = [ (MonotonicClock, getMonoClock)
    , (MemoryStats, readProcStatM)
    , (ProcessStats, readProcStats)
    , (IOStats, readProcIO)
    ]

```

```

pathProc :: FilePath
pathProc = "/proc/"
pathProcStat :: ProcessID  $\rightarrow$  FilePath
pathProcStat pid = pathProc </> (show pid) </> "stat"
pathProcStatM :: ProcessID  $\rightarrow$  FilePath
pathProcStatM pid = pathProc </> (show pid) </> "statm"

```

```
pathProcIO :: ProcessID → FilePath
pathProcIO pid = pathProc </ > (show pid) </ > "io"
```

Reading from a file in /proc/<pid >

```
readProcList :: FilePath → IO [Integer]
readProcList fp = do
  cs ← readFile fp
  return $ map (λs → maybe 0 id $ (readMaybe s :: Maybe Integer)) (words cs)
```

readProcStatM - /proc/<pid >/statm

```
/proc/[pid]/statm
Provides information about memory usage, measured in pages. The columns are:
size      (1) total program size
           (same as VmSize in /proc/[pid]/status)
resident  (2) resident set size
           (same as VmRSS in /proc/[pid]/status)
shared    (3) number of resident shared pages (i.e., backed by a file)
           (same as RssFile+RssShmem in /proc/[pid]/status)
text      (4) text (code)
lib       (5) library (unused since Linux 2.6; always 0)
data      (6) data + stack
dt        (7) dirty pages (unused since Linux 2.6; always 0)
```

```
readProcStatM :: IO [Counter]
readProcStatM = do
  pid ← getProcessID
  ps0 ← readProcList (pathProcStatM pid)
  let ps = zip colnames ps0
  psUseful = filter (("unused" ≠) ∘ fst) ps
  return $ map (λ(n,i) → Counter MemoryCounter n (PureI i)) psUseful
where
  colnames :: [Text]
  colnames = ["size", "resident", "shared", "text", "unused", "data", "unused"]
```

readProcStats - //proc//<pid >//stat

```
/proc/[pid]/stat
Status information about the process. This is used by ps(1). It is defined in the kernel source file
fs/proc/array.c.
```

The fields, in order, with their proper scanf(3) format specifiers, are listed below. Whether or not certain of these fields display valid information is governed by a ptrace access mode PTRACE_MODE_READ_FSCREDS | PTRACE_MODE_NOAUDIT check (refer to ptrace(2)). If the check denies access, then the field value is displayed as 0. The affected fields are indicated with the marking [PT].

- (1) pid %d
The process ID.
- (2) comm %s
The filename of the executable, in parentheses. This is visible whether or not the executable is swapped out.

- (3) state %c
One of the following characters, indicating process state:
- R Running
 - S Sleeping in an interruptible wait
 - D Waiting in uninterruptible disk sleep
 - Z Zombie
 - T Stopped (on a signal) or (before Linux 2.6.33) trace stopped
 - t Tracing stop (Linux 2.6.33 onward)
 - W Paging (only before Linux 2.6.0)
 - X Dead (from Linux 2.6.0 onward)
 - x Dead (Linux 2.6.33 to 3.13 only)
 - K Wakekill (Linux 2.6.33 to 3.13 only)
 - W Waking (Linux 2.6.33 to 3.13 only)
 - P Parked (Linux 3.9 to 3.13 only)
- (4) ppid %d
The PID of the parent of this process.
- (5) pgrp %d
The process group ID of the process.
- (6) session %d
The session ID of the process.
- (7) tty_nr %d
The controlling terminal of the process. (The minor device number is contained in the combination of bits 31 to 20 and 7 to 0; the major device number is in bits 15 to 8.)
- (8) tpgid %d
The ID of the foreground process group of the controlling terminal of the process.
- (9) flags %u
The kernel flags word of the process. For bit meanings, see the PF_* defines in the Linux kernel source file include/linux/sched.h. Details depend on the kernel version.

The format for this field was %lu before Linux 2.6.
- (10) minflt %lu
The number of minor faults the process has made which have not required loading a memory page from disk.
- (11) cminflt %lu
The number of minor faults that the process's waited-for children have made.
- (12) majflt %lu
The number of major faults the process has made which have required loading a memory page from disk.
- (13) cmajflt %lu
The number of major faults that the process's waited-for children have made.
- (14) utime %lu
Amount of time that this process has been scheduled in user mode, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)). This includes guest time, guest_time (time spent running a virtual CPU, see below), so that applications that are not aware of the guest time field do

- not lose that time from their calculations.
- (15) stime %lu
Amount of time that this process has been scheduled in kernel mode, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (16) cutime %ld
Amount of time that this process's waited-for children have been scheduled in user mode, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`). (See also `times(2)`.) This includes guest time, `cguest_time` (time spent running a virtual CPU, see below).
- (17) cstime %ld
Amount of time that this process's waited-for children have been scheduled in kernel mode, measured in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).
- (18) priority %ld
(Explanation for Linux 2.6) For processes running a real-time scheduling policy (policy below; see `sched_setscheduler(2)`), this is the negated scheduling priority, minus one; that is, a number in the range -2 to -100, corresponding to real-time priorities 1 to 99. For processes running under a non-real-time scheduling policy, this is the raw nice value (`setpriority(2)`) as represented in the kernel. The kernel stores nice values as numbers in the range 0 (high) to 39 (low), corresponding to the user-visible nice range of -20 to 19.
- (19) nice %ld
The nice value (see `setpriority(2)`), a value in the range 19 (low priority) to -20 (high priority).
- (20) num_threads %ld
Number of threads in this process (since Linux 2.6). Before kernel 2.6, this field was hard coded to 0 as a placeholder for an earlier removed field.
- (21) itrealvalue %ld
The time in jiffies before the next `SIGALRM` is sent to the process due to an interval timer. Since kernel 2.6.17, this field is no longer maintained, and is hard coded as 0.
- (22) starttime %llu
The time the process started after system boot. In kernels before Linux 2.6, this value was expressed in jiffies. Since Linux 2.6, the value is expressed in clock ticks (divide by `sysconf(_SC_CLK_TCK)`).

The format for this field was %lu before Linux 2.6.
- (23) vsize %lu
Virtual memory size in bytes.
- (24) rss %ld
Resident Set Size: number of pages the process has in real memory. This is just the pages which count toward text, data, or stack space. This does not include pages which have not been demand-loaded in, or which are swapped out.
- (25) rsslim %lu
Current soft limit in bytes on the rss of the process; see the description of `RLIMIT_RSS` in `getrlimit(2)`.
- (26) startcode %lu [PT]
The address above which program text can run.
- (27) endcode %lu [PT]
The address below which program text can run.
- (28) startstack %lu [PT]
The address of the start (i.e., bottom) of the stack.
- (29) kstkesp %lu [PT]
The current value of ESP (stack pointer), as found in the kernel stack page for the process.
- (30) kstkeip %lu [PT]
The current EIP (instruction pointer).

- (31) signal %lu
The bitmap of pending signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.
- (32) blocked %lu
The bitmap of blocked signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.
- (33) sigignore %lu
The bitmap of ignored signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.
- (34) sigcatch %lu
The bitmap of caught signals, displayed as a decimal number. Obsolete, because it does not provide information on real-time signals; use /proc/[pid]/status instead.
- (35) wchan %lu [PT]
This is the "channel" in which the process is waiting. It is the address of a location in the kernel where the process is sleeping. The corresponding symbolic name can be found in /proc/[pid]/wchan.
- (36) nswap %lu
Number of pages swapped (not maintained).
- (37) cnswap %lu
Cumulative nswap for child processes (not maintained).
- (38) exit_signal %d (since Linux 2.1.22)
Signal to be sent to parent when we die.
- (39) processor %d (since Linux 2.2.8)
CPU number last executed on.
- (40) rt_priority %u (since Linux 2.5.19)
Real-time scheduling priority, a number in the range 1 to 99 for processes scheduled under a real-time policy, or 0, for non-real-time processes (see sched_setscheduler(2)).
- (41) policy %u (since Linux 2.5.19)
Scheduling policy (see sched_setscheduler(2)). Decode using the SCHED_* constants in linux/sched.h.

The format for this field was %lu before Linux 2.6.22.
- (42) delayacct_blkio_ticks %llu (since Linux 2.6.18)
Aggregated block I/O delays, measured in clock ticks (centiseconds).
- (43) guest_time %lu (since Linux 2.6.24)
Guest time of the process (time spent running a virtual CPU for a guest operating system), measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).
- (44) cguest_time %ld (since Linux 2.6.24)
Guest time of the process's children, measured in clock ticks (divide by sysconf(_SC_CLK_TCK)).
- (45) start_data %lu (since Linux 3.3) [PT]
Address above which program initialized and uninitialized (BSS) data are placed.
- (46) end_data %lu (since Linux 3.3) [PT]
Address below which program initialized and uninitialized (BSS) data are placed.
- (47) start_brk %lu (since Linux 3.3) [PT]
Address above which program heap can be expanded with brk(2).
- (48) arg_start %lu (since Linux 3.5) [PT]
Address above which program command-line arguments (argv) are placed.
- (49) arg_end %lu (since Linux 3.5) [PT]

Address below program command-line arguments (argv) are placed.

- (50) env_start %lu (since Linux 3.5) [PT]
Address above which program environment is placed.
- (51) env_end %lu (since Linux 3.5) [PT]
Address below which program environment is placed.
- (52) exit_code %d (since Linux 3.5) [PT]
The thread's exit status in the form reported by waitpid(2).

readProcStats :: IO [Counter]

readProcIO - //proc//<pid >//io

/proc/[pid]/io (since kernel 2.6.20)

This file contains I/O statistics for the process, for example:

```
# cat /proc/3828/io
rchar: 323934931
wchar: 323929600
syscr: 632687
syscw: 632675
read_bytes: 0
write_bytes: 323932160
cancelled_write_bytes: 0
```

The fields are as follows:

rchar: characters read

The number of bytes which this task has caused to be read from storage. This is simply the sum of bytes which this process passed to read(2) and similar system calls. It includes things such as terminal I/O and is unaffected by whether or not actual physical disk I/O was required (the read might have been satisfied from pagecache).

wchar: characters written

The number of bytes which this task has caused, or shall cause to be written to disk. Similar caveats apply here as with rchar.

syscr: read syscalls

Attempt to count the number of read I/O operations—that is, system calls such as read(2) and pread(2).

syscw: write syscalls
 Attempt to count the number of write I/O operations—that is, system calls such as write(2) and pwrite(2).

read_bytes: bytes read
 Attempt to count the number of bytes which this process really did cause to be fetched from the storage layer. This is accurate for block-backed filesystems.

write_bytes: bytes written
 Attempt to count the number of bytes which this process caused to be sent to the storage layer.

cancelled_write_bytes:
 The big inaccuracy here is truncate. If a process writes 1MB to a file and then deletes the file, it will in fact perform no writeout. But it will have been accounted as having caused 1MB of write. In other words: this field represents the number of bytes which this process caused to not happen, by truncating pagecache. A task can cause "negative" I/O too. If this task truncates some dirty pagecache, some I/O which another task has been accounted for (in its write_bytes) will not be happening.

Note: In the current implementation, things are a bit racy on 32-bit systems: if process A reads process B's /proc/[pid]/io while process B is updating one of these 64-bit counters, process A could see an intermediate result.

Permission to access this file is governed by a ptrace access mode PTRACE_MODE_READ_FSCREDS check; see ptrace(2).

```
readProcIO :: IO [Counter]
readProcIO = do
  pid ← getProcessID
  ps0 ← readProcList (pathProcIO pid)
  let ps = zip3 colnames ps0 units
  return $ map (\(n,i,u) → Counter IOCounter n (u i)) ps
where
  colnames :: [Text]
  colnames = [ "rchar", "wchar", "syscr", "syscw", "rbytes", "wbytes", "cxwbytes" ]
  units = [ Bytes, Bytes, PureI, PureI, Bytes, Bytes, Bytes ]
```

1.4.10 Cardano.BM.Data.Aggregated

Measurable

A **Measurable** may consist of different types of values.

```
data Measurable = Microseconds Integer
  | Seconds Integer
  | Bytes Integer
  | PureI Integer
  | PureD Double
deriving (Eq, Ord, Generic, ToJSON)
```

Measurable can be transformed to an integral value.

```
getInteger :: Measurable → Integer
getInteger (Microseconds a) = a
getInteger (Seconds a) = a
```

```

getInteger (Bytes a)    = a
getInteger (PureI a)    = a
getInteger (PureD a)    = round a

```

Measurable can be transformed to a rational value.

```

getDouble :: Measurable → Double
getDouble (Microseconds a) = fromInteger a
getDouble (Seconds a)      = fromInteger a
getDouble (Bytes a)        = fromInteger a
getDouble (PureI a)        = fromInteger a
getDouble (PureD a)        = a

```

It is a numerical value, thus supports functions to operate on numbers.

```

instance Num Measurable where
  (+) (Microseconds a) (Microseconds b) = Microseconds (a + b)
  (+) (Seconds a) (Seconds b) = Seconds (a + b)
  (+) (Bytes a) (Bytes b) = Bytes (a + b)
  (+) (PureI a) (PureI b) = PureI (a + b)
  (+) (PureD a) (PureD b) = PureD (a + b)
  (+) _ _ = error "Trying to add values with different units"
  (*) (Microseconds a) (Microseconds b) = Microseconds (a * b)
  (*) (Seconds a) (Seconds b) = Seconds (a * b)
  (*) (Bytes a) (Bytes b) = Bytes (a * b)
  (*) (PureI a) (PureI b) = PureI (a * b)
  (*) (PureD a) (PureD b) = PureD (a * b)
  (*) _ _ = error "Trying to multiply values with different units"
  abs (Microseconds a) = Microseconds (abs a)
  abs (Seconds a) = Seconds (abs a)
  abs (Bytes a) = Bytes (abs a)
  abs (PureI a) = PureI (abs a)
  abs (PureD a) = PureD (abs a)
  signum (Microseconds a) = Microseconds (signum a)
  signum (Seconds a) = Seconds (signum a)
  signum (Bytes a) = Bytes (signum a)
  signum (PureI a) = PureI (signum a)
  signum (PureD a) = PureD (signum a)
  negate (Microseconds a) = Microseconds (negate a)
  negate (Seconds a) = Seconds (negate a)
  negate (Bytes a) = Bytes (negate a)
  negate (PureI a) = PureI (negate a)
  negate (PureD a) = PureD (negate a)
  fromInteger = PureI

```

Pretty printing of **Measurable**.

```

instance Show Measurable where
  show = showSI

```

```

showUnits :: Measurable → String
showUnits (Microseconds _) = " s"
showUnits (Seconds _) = " s"
showUnits (Bytes _) = " B"
showUnits (PureI _) = ""
showUnits (PureD _) = ""
-- show in S.I. units
showSI :: Measurable → String
showSI (Microseconds a) = show (fromFloatDigits ((fromInteger a) / (1000000 :: Float))) ++
  showUnits (Seconds a)
showSI v@(Seconds a) = show a ++ showUnits v
showSI v@(Bytes a) = show a ++ showUnits v
showSI v@(PureI a) = show a ++ showUnits v
showSI v@(PureD a) = show a ++ showUnits v

```

Stats

```

data Stats = Stats {
  flast :: Measurable,
  fmin :: Measurable,
  fmax :: Measurable,
  fcount :: Integer,
  fsum_A :: Double,
  fsum_B :: Double
} deriving (Eq, Generic, ToJSON, Show)

meanOfStats :: Stats → Double
meanOfStats s = fsum_A s

stdevOfStats :: Stats → Double
stdevOfStats s =
  if fcount s < 2
  then 0
  else sqrt $ (fsum_B s) / (fromInteger $ (fcount s) - 1)

```

instance Semigroup Stats disabled for the moment, because not needed.

We use a parallel algorithm to update the estimation of mean and variance from two sample statistics. (see https://en.wikipedia.org/wiki/Algorithms_for_calculating_variance#Parallel_algorithm)

```

instance Semigroup Stats where
  (<>) a b = let counta = fcount a
             countb = fcount b
             newcount = counta + countb
             delta = fsum_A b - fsum_A a
             in

```

```

Stats {flast = flast b-- right associative
      ,fmin   = min (fmin a) (fmin b)
      ,fmax   = max (fmax a) (fmax b)
      ,fcount = newcount
      ,fsum_A = fsum_A a + (delta / fromInteger newcount)
      ,fsum_B = fsum_B a + fsum_B b + (delta * delta) * (fromInteger (counta * countb) / fromInteger newcount)
      }

```

```
stats2Text :: Stats → Text
```

```

stats2Text s@(Stats slast smin smax scount _ _) =
  pack $
    "{ last = " ++ show slast ++
    ", min = " ++ show smin ++
    ", max = " ++ show smax ++
    ", mean = " ++ show (meanOfStats s) ++ showUnits slast ++
    ", std-dev = " ++ show (stddevOfStats s) ++
    ", count = " ++ show scount ++
    " }"

```

Exponentially Weighted Moving Average (EWMA)

```

data EWMA = EmptyEWMA {alpha :: Double}
  | EWMA {alpha :: Double
        ,avg :: Measurable
        } deriving (Show, Eq, Generic, ToJSON)

```

Aggregated

```

data Aggregated = AggregatedStats Stats
  | AggregatedEWMA EWMA
  deriving (Eq, Generic, ToJSON)

```

instance Semigroup Aggregated disabled for the moment, because not needed.

```

instance Semigroup Aggregated where
  (<>) (AggregatedStats a) (AggregatedStats b) =
    AggregatedStats (a <> b)
  (<>) _ _ = error "Cannot combine different objects"

```

```
singletonStats :: Measurable → Aggregated
```

```

    ,fsum_B = 0
  }
in
  AggregatedStats stats

```

```

instance Show Aggregated where
  show (AggregatedStats astats) =
    "{ stats = " ++ show astats ++ " }"
  show (AggregatedEWMA a) = show a

```

1.4.11 Cardano.BM.Data.Backend

Accepts a NamedLogItem

Instances of this type class accept a **NamedLogItem** and deal with it.

```

class IsEffectuator t where
  effectuate :: t → NamedLogItem → IO ()
  effectuatefrom :: forall s ◦ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  default effectuatefrom :: forall s ◦ (IsEffectuator s) ⇒ t → NamedLogItem → s → IO ()
  effectuatefrom t nli _ = effectuate t nli

```

Declaration of a Backend

A backend is life-cycle managed, thus can be *realized* and *unrealized*.

```

class (IsEffectuator t) ⇒ IsBackend t where
  typeof    :: t → BackendKind
  realize    :: Configuration → IO t
  realizefrom :: forall s ◦ (IsEffectuator s) ⇒ Trace IO → s → IO t
  default realizefrom :: forall s ◦ (IsEffectuator s) ⇒ Trace IO → s → IO t
  realizefrom (ctx, _) _ = realize (configuration ctx)
  unrealize :: t → IO ()

```

Backend

This data structure for a backend defines its behaviour as an **IsEffectuator** when processing an incoming message, and as an **IsBackend** for unrealizing the backend.

```

data Backend = MkBackend
  { bEffectuate :: NamedLogItem → IO ()
  , bUnrealize :: IO ()
  }

```

1.4.12 Cardano.BM.Data.Configuration

Data structure to help parsing configuration files.

Representation

```

type Port = Int
data Representation = Representation
  { minSeverity    :: Severity
  , rotation      :: RotationParameters
  , setupScribes  :: [ScribeDefinition]
  , defaultScribes :: [(ScribeKind, Text)]
  , setupBackends :: [BackendKind]
  , defaultBackends :: [BackendKind]
  , hasEKG       :: Maybe Port
  , hasGUI       :: Maybe Port
  , options      :: HM.HashMap Text Object
  }
deriving (Generic, Show, ToJSON, FromJSON)

```

parseRepresentation

```

parseRepresentation :: FilePath → IO Representation
parseRepresentation fp = do
  repr :: Representation ← decodeFileThrow fp
  return $ implicit_fill_representation repr

```

after parsing the configuration representation we implicitly correct it.

```

implicit_fill_representation :: Representation → Representation
implicit_fill_representation =
  remove_ekgview_if_not_defined ∘
  filter_duplicates_from_backends ∘
  filter_duplicates_from_scribes ∘
  union_setup_and_usage_backends ∘
  add_ekgview_if_port_defined ∘
  add_katip_if_any_scribes
where
  filter_duplicates_from_backends r =
    r { setupBackends = mkUniq $ setupBackends r }
  filter_duplicates_from_scribes r =
    r { setupScribes = mkUniq $ setupScribes r }
  union_setup_and_usage_backends r =
    r { setupBackends = setupBackends r <> defaultBackends r }
  remove_ekgview_if_not_defined r =
    case hasEKG r of
      Nothing → r { defaultBackends = filter (λbk → bk ≠ EKGViewBK) (defaultBackends r)

```

```

add_ekgview_if_port_defined r =
  case hasEKG r of
    Nothing  $\rightarrow$  r
    Just _  $\rightarrow$  r {setupBackends = setupBackends r <> [EKGVViewBK]}
add_katip_if_any_scribes r =
  if (any  $\neg$  [null $ setupScribes r, null $ defaultScribes r])
  then r {setupBackends = setupBackends r <> [KatipBK]}
  else r
mkUniq :: Ord a  $\Rightarrow$  [a]  $\rightarrow$  [a]
mkUniq = Set.toList  $\circ$  Set.fromList

```

1.4.13 Cardano.BM.Data.Counter

Counter

```

data Counter = Counter
  { cType :: CounterType
  , cName :: Text
  , cValue :: Measurable
  }
  deriving (Eq, Show, Generic, ToJSON)

data CounterType = MonotonicClockTime
  | MemoryCounter
  | StatInfo
  | IOCounter
  | CpuCounter
  | RTSSStats
  deriving (Eq, Show, Generic, ToJSON)

instance ToJSON Microsecond where
  toJSON = toJSON  $\circ$  toMicroseconds
  toEncoding = toEncoding  $\circ$  toMicroseconds

```

Names of counters

```

nameCounter :: Counter  $\rightarrow$  Text
nameCounter (Counter MonotonicClockTime _) = "Time-interval"
nameCounter (Counter MemoryCounter _) = "Mem"
nameCounter (Counter StatInfo _) = "Stat"
nameCounter (Counter IOCounter _) = "IO"
nameCounter (Counter CpuCounter _) = "Cpu"
nameCounter (Counter RTSSStats _) = "RTS"

```

CounterState

```

data CounterState = CounterState {
  csIdentifier :: Unique
  , csCounters :: [Counter]
}
deriving (Generic, ToJSON)
instance ToJSON Unique where
  toJSON = toJSON o hashUnique
  toEncoding = toEncoding o hashUnique
instance Show CounterState where
  show cs = (show o hashUnique) (csIdentifier cs)
  <> " => " <> (show $ csCounters cs)

```

Difference between counters

```

diffCounters :: [Counter] → [Counter] → [Counter]
diffCounters openings closings =
  getCountersDiff openings closings
where
  getCountersDiff :: [Counter]
    → [Counter]
    → [Counter]
  getCountersDiff as bs =
    let
      getName counter = nameCounter counter <> cName counter
      asNames = map getName as
      aPairs = zip asNames as
      bsNames = map getName bs
      bs' = zip bsNames bs
      bPairs = HM.fromList bs'
    in
      catMaybes $ (flip map) aPairs $ λ(name, Counter _ _ startValue) →
        case HM.lookup name bPairs of
          Nothing → Nothing
          Just counter → let endValue = cValue counter
                        in Just counter {cValue = endValue - startValue}

```

1.4.14 Cardano.BM.Data.LogItem**LoggerName**

```

type LoggerName = Text

```

NamedLogItem

```
type NamedLogItem = LogNamed LogObject
```

LogItem

```
TODO liPayload :: ToObject
```

```
data LogItem = LogItem
  { liSelection :: LogSelection
  , liSeverity :: Severity
  , liPayload :: Text -- TODO should become ToObject
  } deriving (Show, Generic, ToJSON)
```

```
data LogSelection =
  Public -- only to public logs.
  | PublicUnsafe -- only to public logs, not console.
  | Private -- only to private logs.
  | Both -- to public and private logs.
  deriving (Show, Generic, ToJSON, FromJSON)
```

LogObject

```
data LogPrims = LogMessage LogItem
  | LogValue Text Measurable
  deriving (Generic, Show, ToJSON)
data LogObject = LP LogPrims
  | ObserveOpen CounterState
  | ObserveDiff CounterState
  | ObserveClose CounterState
  | AggregatedMessage [(Text, Aggregated)]
  | KillPill
  deriving (Generic, Show, ToJSON)
```

LogNamed

A **LogNamed** contains of a context name and some log item.

```
data LogNamed item = LogNamed
  { lnName :: LoggerName
  , lnItem :: item
  } deriving (Show)
deriving instance Generic item => Generic (LogNamed item)
deriving instance (ToJSON item, Generic item) => ToJSON (LogNamed item)
```

1.4.15 Cardano.BM.Data.Observable**ObservableInstance**

```

data ObservableInstance = MonotonicClock
  | MemoryStats
  | ProcessStats
  | IOStats
  | GhcRtsStats
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON, Read)

```

1.4.16 Cardano.BM.Data.Output**OutputKind**

```

data OutputKind = TVarList (STM.TVar [LogObject])
  | TVarListNamed (STM.TVar [LogNamed LogObject])
  deriving (Eq)

```

ScribeKind

This identifies katip's scribes by type.

```

data ScribeKind = FileTextSK
  | FileJsonSK
  | StdoutSK
  | StderrSK
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)

```

ScribeId

A scribe is identified by **ScribeKind** x *Filename*

```

type ScribeId = Text -- (ScribeKind :: Filename)

```

ScribeDefinition

This identifies katip's scribes by type.

```

data ScribeDefinition = ScribeDefinition
  { scKind :: ScribeKind
  , scName :: Text
  , scRotation :: Maybe RotationParameters
  }
  deriving (Generic, Eq, Ord, Show, FromJSON, ToJSON)

```

1.4.17 Cardano.BM.Data.Severity

Severity

The intended meaning of severity codes:

Debug *detailed information about values and decision flow* **Info** general information of events; progressing properly Notice *needs attention; something \rightarrow progressing properly* **Warning** may continue into an error condition if continued Error *unexpected set of event or condition occurred* **Critical** error condition causing degrade of operation Alert *a subsystem is no longer operating correctly, likely requires manual* at this point, the system can never progress without additional intervention

We were informed by the Syslog taxonomy: https://en.wikipedia.org/wiki/Syslog#Severity_level

```
data Severity = Debug
  | Info
  | Notice
  | Warning
  | Error
  | Critical
  | Alert
  | Emergency
  deriving (Show, Eq, Ord, Generic, ToJSON, Read)

instance FromJSON Severity where
  parseJSON = withText "severity" $ \case
    "Debug"    → pure Debug
    "Info"     → pure Info
    "Notice"   → pure Notice
    "Warning"  → pure Warning
    "Error"    → pure Error
    "Critical" → pure Critical
    "Alert"    → pure Alert
    "Emergency" → pure Emergency
    _          → pure Info-- catch all
```

1.4.18 Cardano.BM.Data.SubTrace

SubTrace

```
data NameSelector = Exact Text | StartsWith Text | EndsWith Text | Contains Text
  | Named Text-- LP (LogValue (name value))
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data NameOperator = Drop NameSelector | Unhide NameSelector
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
data SubTrace = Neutral
  | UntimedTrace
  | NoTrace
  | TeeTrace LoggerName
  | FilterTrace [NameOperator]
  | DropOpening
```

```
| ObservableTrace [ObservableInstance]
  deriving (Generic, Show, FromJSON, ToJSON, Read, Eq)
```

1.4.19 Cardano.BM.Data.Trace

Trace

A **Trace** consists of a **TraceContext** and a **TraceNamed** in *m*.

```
type Trace m = (TraceContext, TraceNamed m)
```

TraceNamed

A **TraceNamed** is a specialized **Contravariant** of type **NamedLogItem**, a **LogNamed** with payload **LogObject**.

```
type TraceNamed m = BaseTrace m (NamedLogItem)
```

TraceContext

We keep the context's name and a reference to the **Configuration** in the **TraceContext**.

```
data TraceContext = TraceContext
  { loggerName :: LoggerName
  , configuration :: Configuration
  , tracetype   :: SubTrace
  , minSeverity :: Severity
  , shutdown    :: IO ()
  }
```

1.4.20 Cardano.BM.Configuration

see **Cardano.BM.Configuration.Model** for the implementation.

```
getOptionOrDefault :: CM.Configuration → Text → Text → IO (Text)
getOptionOrDefault cg name def = do
  opt ← CM.getOption cg name
  case opt of
    Nothing → return def
    Just o  → return o
```

Figure 1.4: Configuration model

1.4.21 Cardano.BM.Configuration.Model

Configuration.Model

```

Internal representation

```

type AggregationMVar = MVar AggregationInternal
newtype Aggregation = Aggregation
  { getAg :: AggregationMVar }
data AggregationInternal = AggregationInternal
  { agQueue :: TBQ.TBQueue (Maybe NamedLogItem)
  , agDispatch :: Async.Async ()
  }

```

Relation from context name to aggregated statistics

We keep the aggregated values (**Aggregated**) for a named context in a *HashMap*.

```

type AggregationMap = HM.HashMap Text AggregatedExpanded

```

Info for Aggregated operations

Apart from the **Aggregated** we keep some valuable info regarding to them; such as when was the last time it was sent.

```
type Timestamp = Word64
data AggregatedExpanded = AggregatedExpanded
  { aeAggregated :: Aggregated
  , aeResetAfter :: Maybe Integer
  , aeLastSent :: Timestamp
  }
```

Aggregation implements effectuate

Aggregation is an **Accepts a NamedLogItem** Enter the log item into the **Aggregation** queue.

```
instance IsEffectuator Aggregation where
  effectuate agg item = do
    ag ← readMVar (getAg agg)
    atomically $ TBQ.writeTBQueue (agQueue ag) $ Just item
```

Aggregation implements Backend functions

Aggregation is an **Declaration of a Backend**

```

Update aggregation

We distinguish an uninitialized from an already initialized aggregation. The latter is properly initialized.

We use Welford's online algorithm to update the estimation of mean and variance of the sample statistics. (see https://en.wikipedia.org/wiki/Algorithms_for_calculating_variance#Welford's_Online)

```

updateAggregation :: Measurable → Aggregated → Maybe Integer → Aggregated
updateAggregation v (AggregatedStats s) resetAfter =
  let count = fcount s
      reset = maybe False (count ≥) resetAfter
  in
  if reset
  then
    singletonStats v
  else
    let newcount = count + 1
        newvalue = getDouble v
        delta = newvalue - fsum_A s
        dincr = (delta / fromInteger newcount)
        delta2 = newvalue - fsum_A s - dincr
    in
    AggregatedStats Stats {flast = v
                          ,fmin = min (fmin s) v
                          ,fmax = max (fmax s) v
                          ,fcount = newcount
                          ,fsum_A = fsum_A s + dincr
                          ,fsum_B = fsum_B s + (delta * delta2)
                          }
updateAggregation v (AggregatedEWMA e) _ =
  AggregatedEWMA $ ewma e v

```

Calculation of EWMA

Following https://en.wikipedia.org/wiki/Moving_average#Exponential_moving_average we calculate the exponential moving average for a series of values Y_t according to:

$$S_t = \begin{cases} Y_1, & t = 1 \\ \alpha \cdot Y_t + (1 - \alpha) \cdot S_{t-1}, & t > 1 \end{cases}$$

The pattern matching below ensures that the **EWMA** will start with the first value passed in, and will not change type, once determined.

```

ewma :: EWMA → Measurable → EWMA
ewma (EmptyEWMA a) v = EWMA a v
ewma (EWMA a (Microseconds s)) (Microseconds y) =
  EWMA a $ Microseconds $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (Seconds s)) (Seconds y) =
  EWMA a $ Seconds $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (Bytes s)) (Bytes y) =
  EWMA a $ Bytes $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (PureI s)) (PureI y) =

```

```
EWMA a $ PureI $ round $ a * (fromInteger y) + (1 - a) * (fromInteger s)
ewma (EWMA a (PureD s)) (PureD y) =
  EWMA a $ PureD $ a * y + (1 - a) * s
ewma _ _ = error "Cannot average on values of different type"
```
